

THE IMAGING TRAIN

ASTROPHOTOGRAPHY

ASTROPHOTOGRAPHY BASICS

- ▶ Understanding FOCAL RATIO and 'speed'
- ▶ found by dividing the focal length by the aperture
 - ▶ Focal length: The length that the light travels inside the telescope, in mm
 - ▶ Aperture: The size of the opening, in mm
- ▶ Ex: Typical 80mm Refractor: 480mm focal length
 - ▶ $480/80 = 6$; f/6
- ▶ Lower numbers equal 'faster' telescopes
 - ▶ This refers to the 'density' of light striking the sensor. The smaller the focal ratio, the more compressed the light is, and the brighter the image will be
 - ▶ So, an **f/5** system can gather light at the image plane **4-times as fast** as an **f/10** system, but the image will be only one-half as large (assuming the same aperture).
 - ▶ Faster = shorter images (subs) = more forgiveness
 - ▶ *However, dimmer stars can only be seen with larger apertures. Focal ratio doesn't matter.

WHAT DO YOU NEED?

- ▶ Mount - something to track the sky.
 - ▶ Should be the majority of your budget
- ▶ Lens - Telescope? Camera Lens?
- ▶ Image plane correction
- ▶ Focusing Ability
- ▶ Filters?
- ▶ Camera
- ▶ Guider?

THE IMAGING TRAIN

MOUNTS

ALT/AZ MOUNTS

- ▶ Alt/Az vs EQ (GEM)
 - ▶ Alt/Az: Ease of use, but limited to very short exposures (30s)
 - ▶ Rotator?
 - ▶ Wedge?
 - ▶ Typically larger PE (periodic error)

GEM MOUNTS

- ▶ Requires more precision with set up - polar alignment
- ▶ Capable of unlimited exposure times
- ▶ Wide range of price (**tends to equal precision**)
- ▶ Worm gear/belt drive
- ▶ Absolute encoders?
- ▶ Divide capacity by half for imaging - for non top-tier gear

STAR TRACKERS

- ▶ iOption Startacker Pro
- ▶ \$299
- ▶ Best with DSLR + Wide lens
- ▶ 2-4min exposures max
- ▶ Good reviews
- ▶ Requires star finding knowledge
- ▶ 6lb Capacity

EQ MOUNTS

- ▶ SKY-WATCHER EQ6-R PRO EQUATORIAL GO-TO MOUNT
- ▶ \$1,595.00
- ▶ Trainable periodic error correction
- ▶ Belt Drive (as opposed to gears)
- ▶ 44lb Capacity
- ▶ Built in DSLR trigger

EQ MOUNTS

- ▶ Celestron CGX
 - ▶ \$2300
 - ▶ 55lbs
 - ▶ Easy to Use
 - ▶ Can be hit or miss
- ▶ Also, Takahashi (used)
- ▶ Losmandy
- ▶ Other iOptron - w/Encoders

EQ MOUNTS – PREMIUM MOUNTS

- ▶ Paramount MyT
- ▶ Astro-Physics Mach1
- ▶ Avalon M-Uno
- ▶ About \$6-7000
- ▶ Different level of fit and finish
- ▶ Only needed for long exposures
- ▶ Better Software

NEXT GEN MOUNTS

- ▶ Rainbow Astro
- ▶ 'Strain Wave Gear' driven
- ▶ Size of star tracker, but full fledged mount
- ▶ Very good tracking, no backlash
- ▶ Packable in a backpack
- ▶ \$4000-6500

MOUNT – FINAL THOUGHTS

- ▶ Look for used equipment
 - ▶ AstroMart - best classifieds
- ▶ Most say at least half your budget
- ▶ Remember - also need a good tripod
- ▶ Try stay at 75% max weight or below
- ▶ Think about the future

THE IMAGING TRAIN

TELESCOPES

LENS

- ▶ Easy to find used lenses
- ▶ Do research on sharpest lens for your needs
- ▶ Least expensive option
- ▶ Start with 200-400mm focal length, or wider
- ▶ You probably already have something reasonable

REFLECTORS

- ▶ Pros
 - ▶ Best Bang for the Buck (largest aperture per cost)
 - ▶ Can be very sharp
 - ▶ Can be very fast (f/3-range)
 - ▶ Good contrast
- ▶ Cons
 - ▶ Can be hard to collimate
 - ▶ Short focal range (back focus)
 - ▶ Bulky/heavy
 - ▶ Diffraction spikes, which some love
 - ▶ Large coma effect - requires correction

NEWTONIANS

- ▶ teleskop-express.de
- ▶ Or, Astro-tech, Orion, or Meade
- ▶ Imaging Newts starting at \$250
- ▶ All Newts require a Coma Corrector
- ▶ Most are f/5 at lower prices

CASSEGARAINS – SCHMIDT CASSEGRAIN

▶ Pros

- ▶ Long focal length = 'zoom'
- ▶ Very large apertures
- ▶ Wide range of focal ratios - f/10-f/2
- ▶ Huge focal range (back focus)
- ▶ Great for galaxies and PNs

▶ Cons

- ▶ Collimation can be difficult
- ▶ Loss of contrast
- ▶ 'Mirror flop'
- ▶ Needs correction/reduction
- ▶ Heavy
- ▶ Dew Magnet

SCT

- ▶ MEADE 8" LX200-ACF (\$1200)
- ▶ Celestron 8" EDGEHD (\$1350)
 - ▶ Locking Primary mirror
 - ▶ Coma free optics
 - ▶ Slow at f/10
 - ▶ Affordable apertures to 14"
- ▶ ** Do not attempt to image with a standard SCT.

THE IMAGING TRAIN

REFRACTORS

PROS

- SUPER-SHARP - HIGHEST OPTICAL QUALITY AVAILABLE IN SMALL TELESCOPES
- COMPACT
- WIDE F.O.V.
- 'NEVER' NEEDS COLLIMATION
- SEALED SYSTEM
- VERY HIGH CONTRAST

CONS

- EXPENSIVE
- CAN PRODUCE FALSE COLORS
- SMALL APERTURES - LARGEST IS 6"
- ALMOST ALWAYS NEED TO REPLACE FOCUSER

80MM REFRACTORS

- ▶ Explore Scientific ED80
 - ▶ Or, Orion ED80 (cheaper, but...)
- ▶ Highly recommended as first imaging scope
- ▶ Very forgiving in terms of tracking and focus
- ▶ Nice, wide (rich) fields
- ▶ Reasonably to very fast
- ▶ Need at least 3 lenses (triplet)
- ▶ Reality - need 4 lenses

THE IMAGING TRAIN

FOCUSERS

FOCUSERS – WHICH IS FOR WHAT?

- ▶ Type - Crayford or Rack & Pinion?
 - ▶ Crayford: Cheaper, smooth - might slip with heavy loads
 - ▶ R&P: Costly, strong - can be jerky if not made well
- ▶ Tube Length
 - ▶ Newts: Require very short tubes (focal range) - 1.5"
 - ▶ Refractors: Can require very long tubes - up to 4.5"
 - ▶ SCT: Short tubes (.75-1.5") needed because rough focus done with built in focuser
- ▶ All imagers use aftermarket focusers.

FOCUSER THOUGHTS

- ▶ You can not focus by eye
 - ▶ The CRZ (critical focus zone) is super small:
 - ▶ $F/R \text{ squared} * 2.2$
 - ▶ $f/5.6 = 68 \text{ microns} = .0027''$
 - ▶ $f.10 = 220 \text{ microns} = .0087''$
 - ▶ Human hair - approx 80 microns
 - ▶ My focuser moves in 1 micron steps
- ▶ Motorized is best, even if hand driven
- ▶ Need correct flange - make sure one is made for your scope!

FOCUSING OPTIONS

- ▶ Attachment motors for focusers
 - ▶ \$200-400
- ▶ DIY: Arduino Focuser 2
- ▶ Bhatinov mask
- ▶ Software assisted:
 - ▶ MetaGuide
 - ▶ SharpCap

THE IMAGING TRAIN

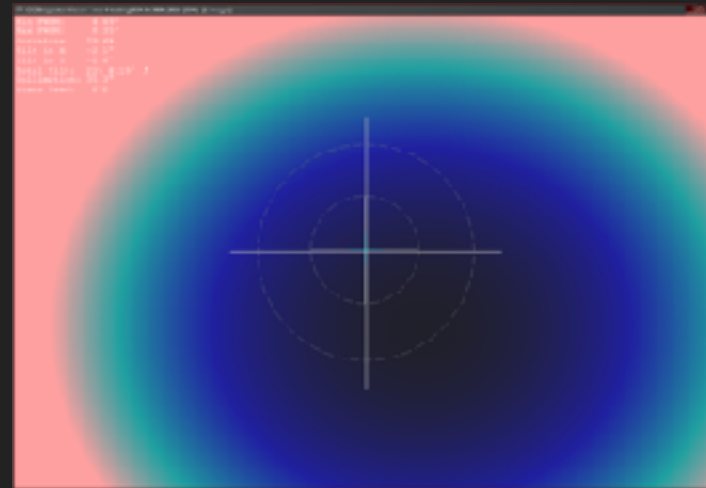

**REDUCERS/CORRECTORS/
FLATTENERS**

REDUCERS/CORRECTORS

- ▶ What do we need?
 - ▶ Refractors: Reducer, Flattener or R/F - often scope-specific, usually .8x
 - ▶ Reflectors: Coma Corrector, Reducer?
 - ▶ SCT, RC: R/C, .67x, .63x, .5x, .33x
- ▶ Corrected SCT: Reducer, .7x

REDUCERS/CORRECTORS

- ▶ Most Importantly:
 - ▶ What is the **back focus** of the device?
 - ▶ How far MUST the sensor be from the back of the device?
 - ▶ Often 55mm (the distance of a t-ring+DSLR)
 - ▶ This will define what equipment can be considered
 - ▶ How large is the **image circle** produced by the device?
 - ▶ Need to insure fully-illuminated and corrected image circle is larger than your sensor to avoid vignetting/coma/distortion.

THE IMAGE TRAIN

CAMERAS

CAMERAS

- ▶ Lots of choices - \$800-\$10,000
- ▶ Mono vs OSC vs DSLR
- ▶ CMOS vs CCD
 - ▶ CCD: Older tech, Noisier, Easier
 - ▶ CMOS: Less noise, Amp Glow
- ▶ Cooling? - 2 stage is best
- ▶ Sealed chamber?
- ▶ Software/Hardware compatible?
- ▶ Size of chip defines F.o.V. - use online tools to simulate

CAMERA CHOICES

- ▶ DSLR: Nikon D5300 - most recommended for Astrowork
 - ▶ Used for \$250
 - ▶ Astro-modded \$450 (Full Spectrum)
 - ▶ Huge Plus - Gigantic sensor
 - ▶ Big minus - no cooling; noisier, needs lots of dark frames
- ▶ BackYard Nikon/EOS \$50
- ▶ ZWO 183MC PRO - Color CMOS
 - ▶ Cooled
 - ▶ \$800
 - ▶ Less and half as large of a sensor
 - ▶ SharpCap Pro \$10/year

CAMERA CHOICES

- ▶ Used 8300-based CCD
 - ▶ QHY9
 - ▶ SBIG ST-8300
 - ▶ \$800ish
 - ▶ BUT - need to remember
 - ▶ Need filters
 - ▶ Filter wheel
 - ▶ Guider

UNDERSTANDING IMAGE SCALE

- ▶ Defined as the number of arc seconds of sky recorded per pixel.
 - ▶ $\text{pixel size (microns)} \times 206.3 / \text{focal length in mm} = \text{image scale in arcsec/pixel}$
- ▶ Proper sampling: Each star should be recorded over 3-4 pixels.
- ▶ Seeing (sky clarity) defines size of star (point spread)
- ▶ Our skies are usually 2-4, so each star, at best, is 2-4 arc-seconds in size.
- ▶ For proper sampling, we need a maximum of a .66 image scale, or each pixel recording .66 arc-sec of sky
- ▶ Proper scale is hard to achieve - software can help (drizzle algorithm)

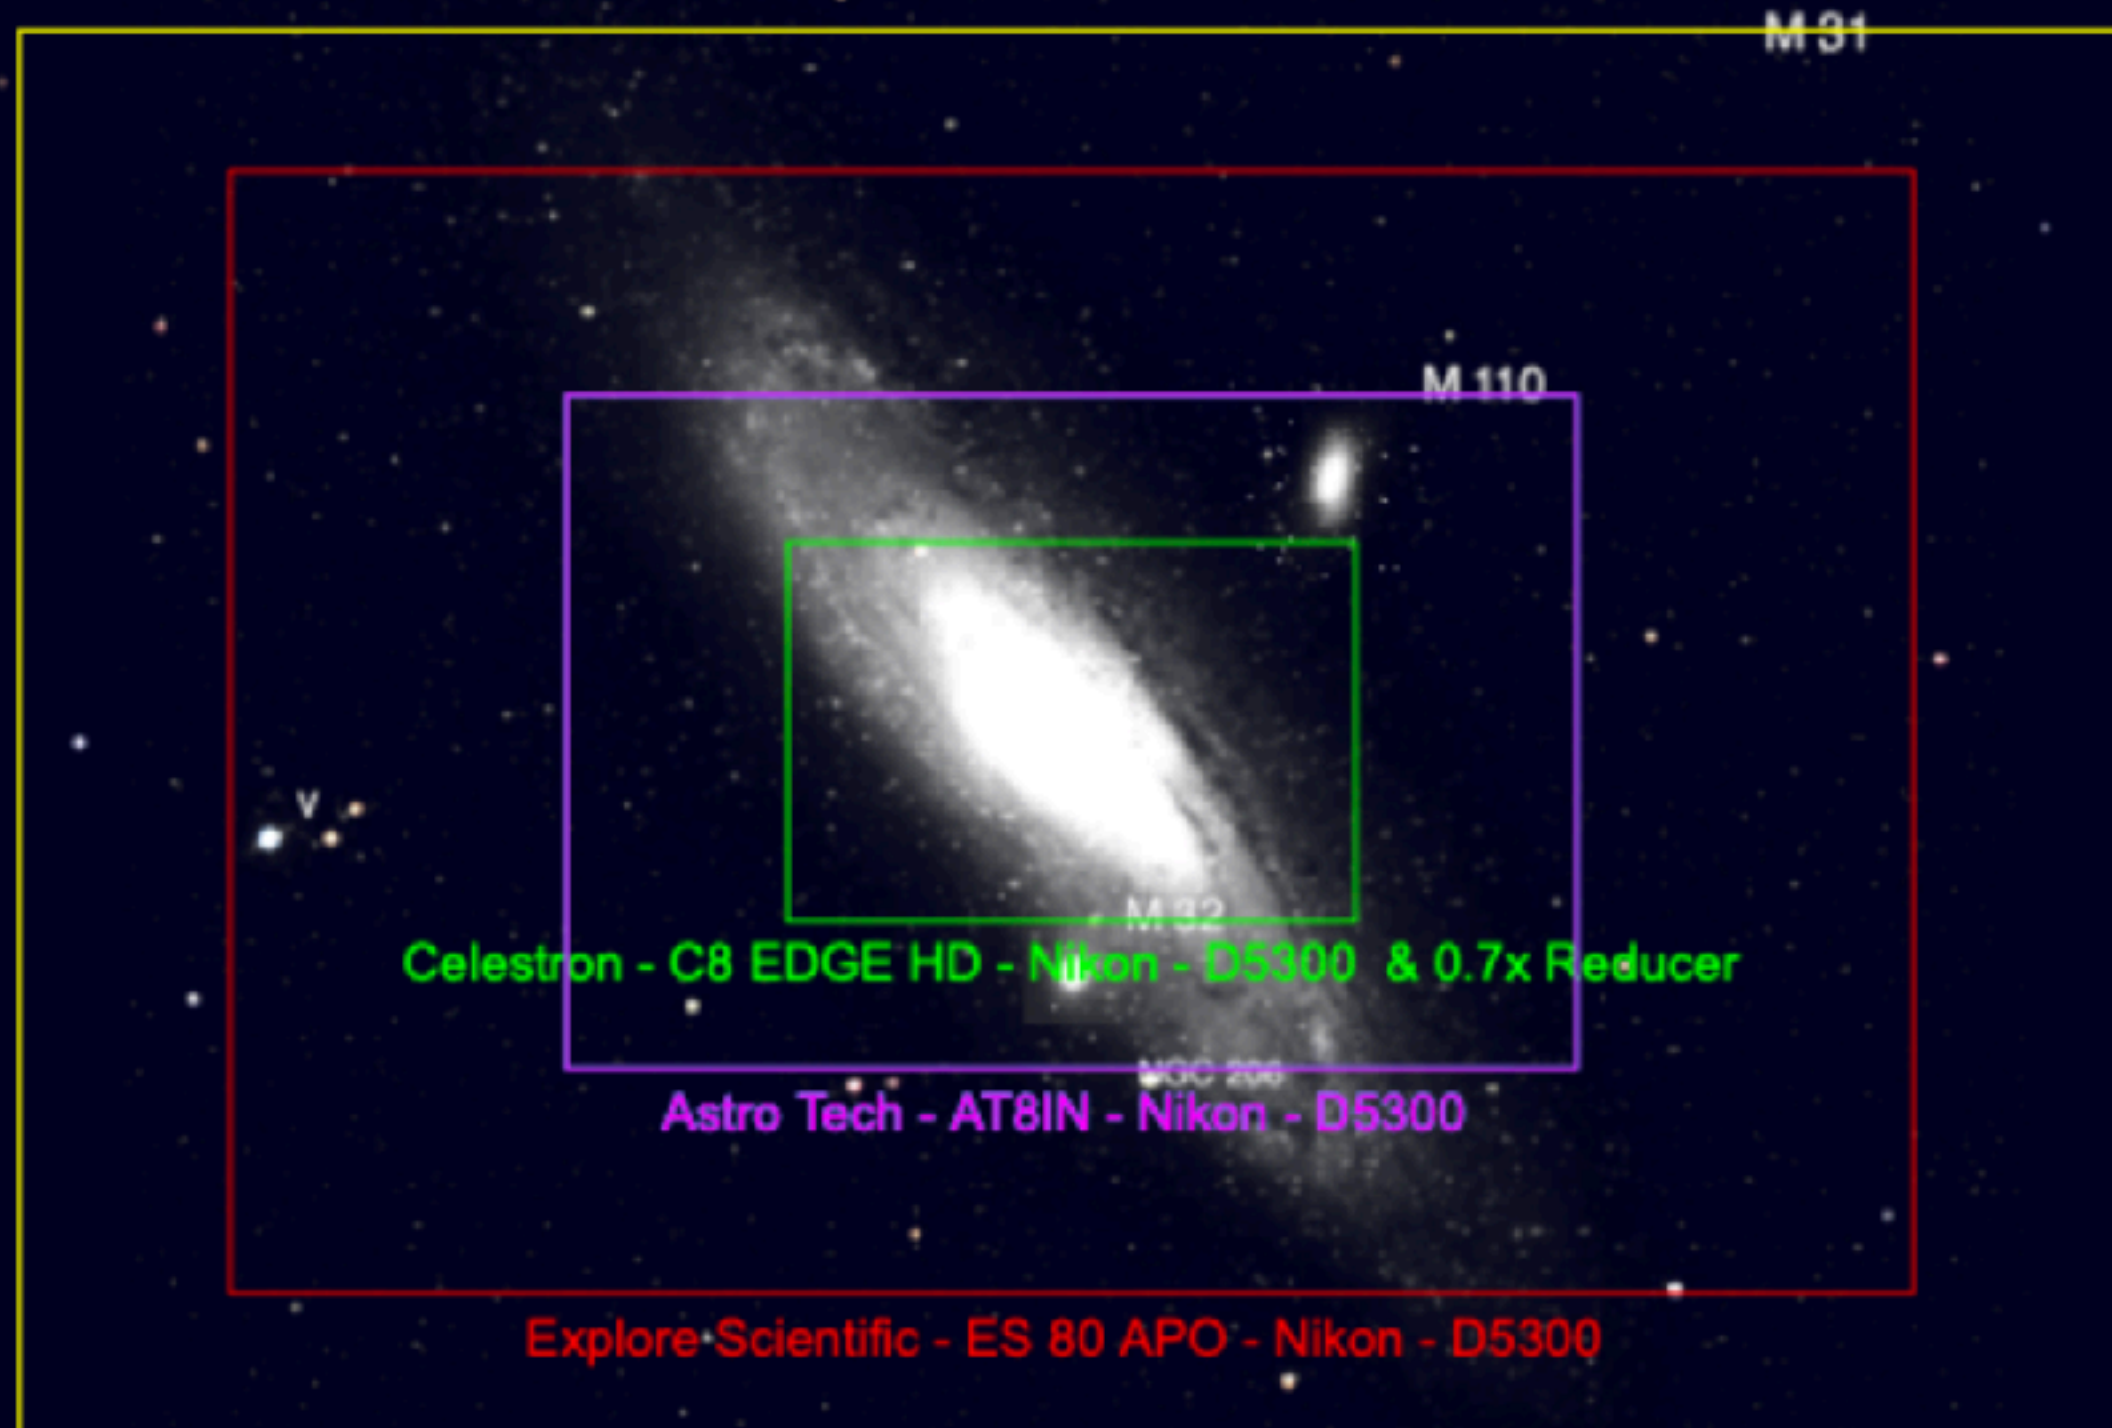

Celestron - C8 EDGE HD - Nikon - D5300 & 0.7x Reducer .57 a/p

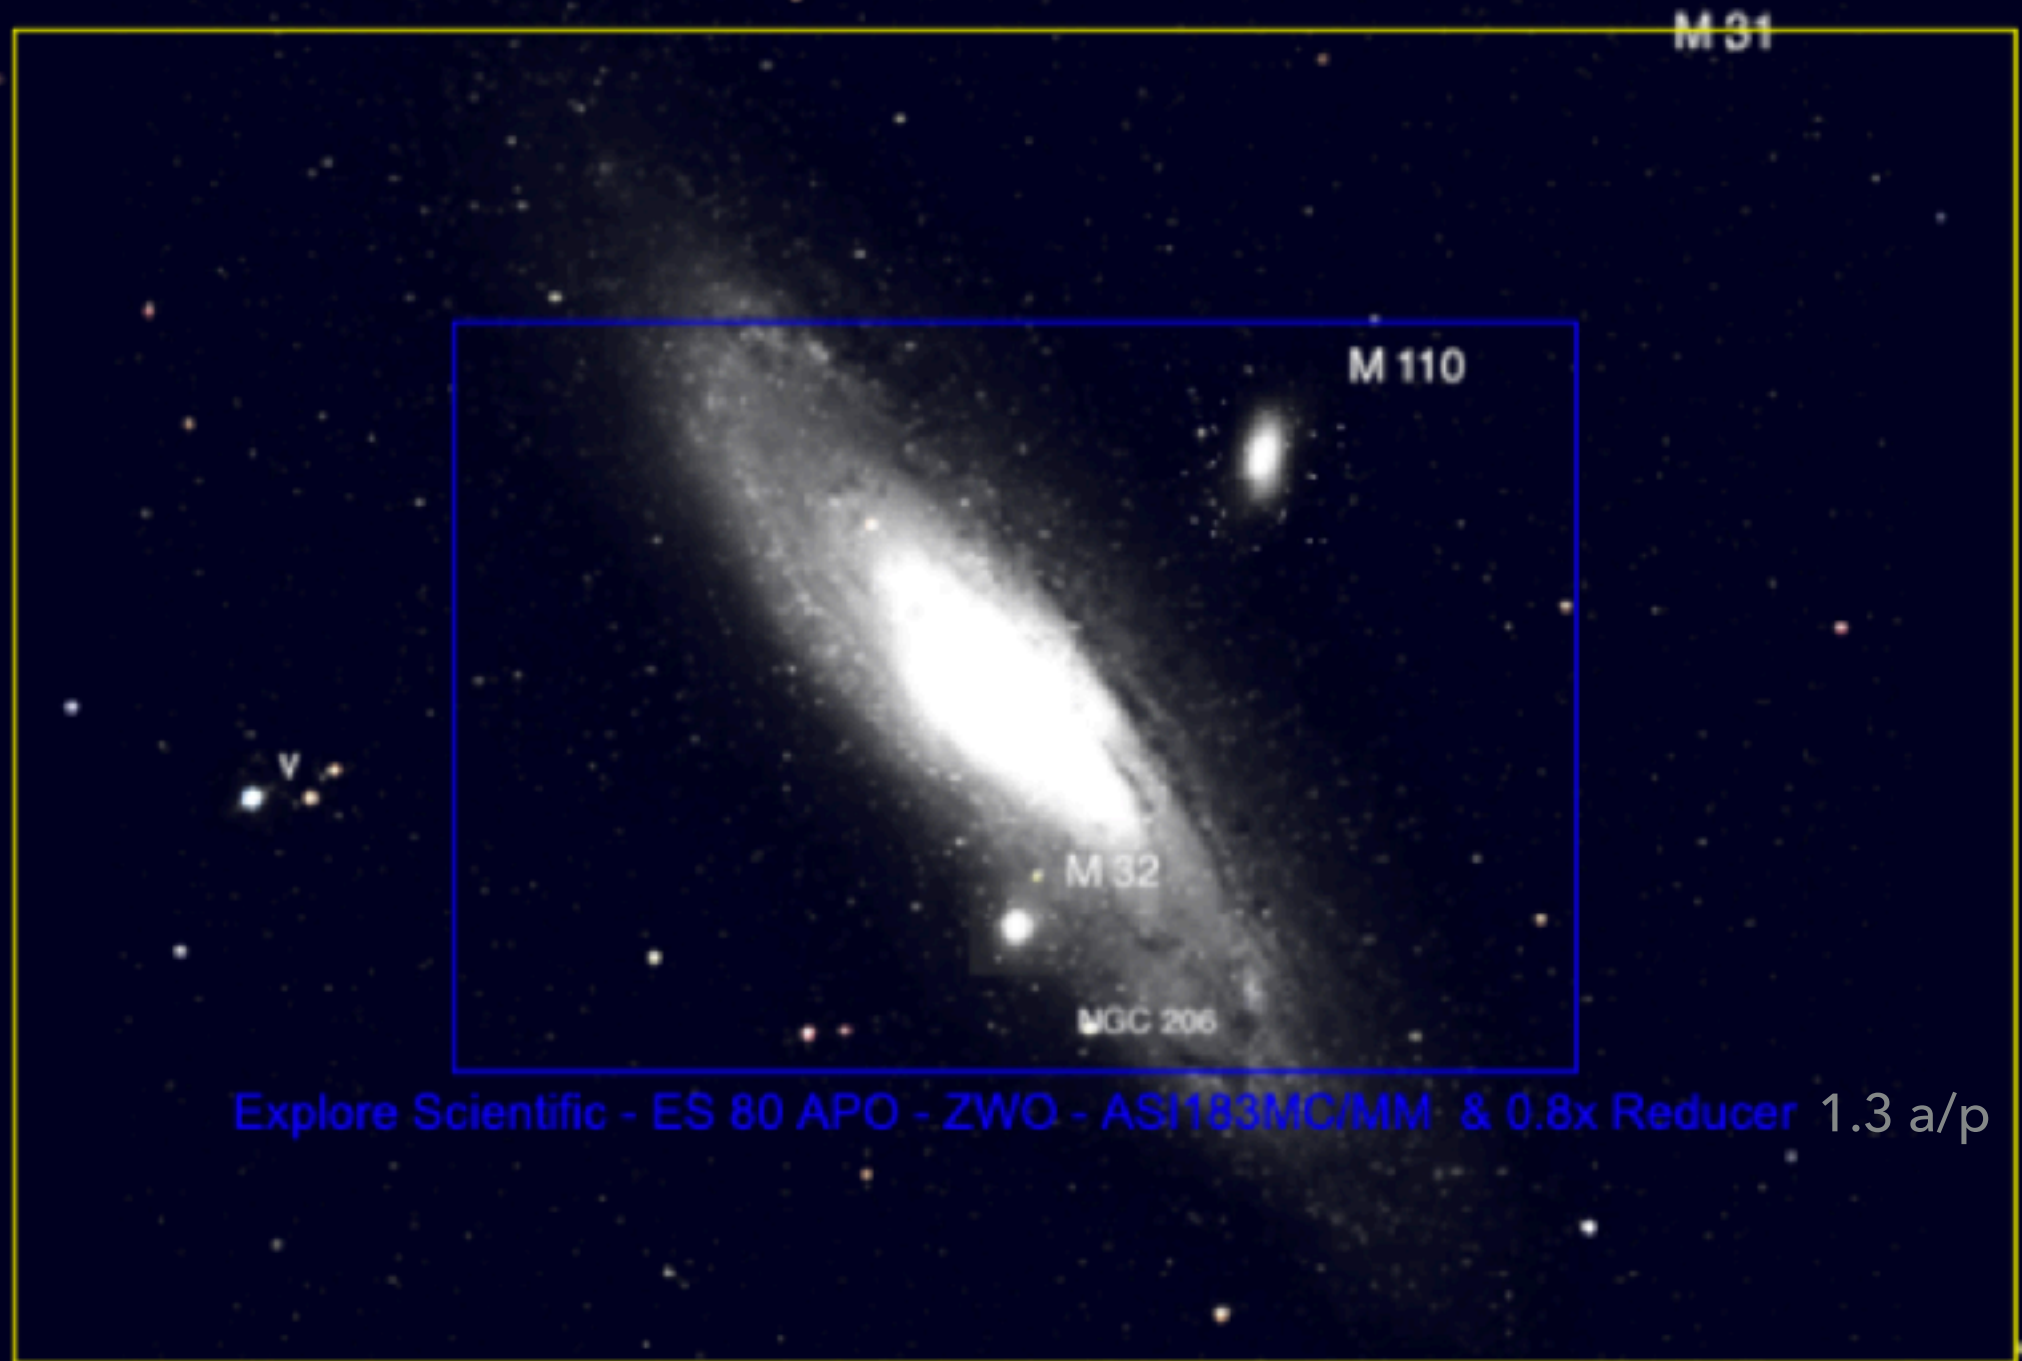

Astro Tech - AT8IN - Nikon - D5300 1.1 a/p

Explore Scientific - ES 80 APO - Nikon - D5300 1.6 a/p

Explore Scientific - ES 80 APO - Nikon - D5300 & 0.8x Reducer 2.1 a/p

Explore Scientific - ES 80 APO - Nikon - D5300 & 0.8x Reducer

Explore Scientific - ES 80 APO - ZWO - ASI183MC/MM & 0.8x Reducer 1.3 a/p

Explore Scientific - ES 80 APO - Nikon - D5300 & 0.8x Reducer 2.1 a/p

200mm f5.6 Nikkor Custom Scope - Nikon - D5300 4.0 a/p

A close-up photograph of an off-axis guider, a precision optical instrument used in astronomy. The device features a large, dark, circular aperture with a smaller, rectangular opening in the center. Several adjustment knobs and screws are visible around the perimeter of the device, indicating its adjustable nature. The background is a plain, light color.

THE IMAGING TRAIN

OFF AXIS GUIDERS

OAG

- ▶ Most important measure is width
- ▶ Otherwise, they are fairly similar
- ▶ Should be in front of filter wheel
- ▶ Eliminated flexure issues
- ▶ Saves weight/bulk
- ▶ **Guiders** - the more sensitive the better
 - ▶ Lodestar X2
 - ▶ Star Shoot Auto-Guider
 - ▶ STi
 - ▶ QHY5-III

The image shows four circular filter wheels arranged in a cluster. Each wheel has a dark, textured metal rim and a central circular filter. The filters are colored red, blue, green, and white. The wheels are slightly overlapping, and the background is a light, neutral color.

THE IMAGING TRAIN

FILTER WHEELS

FILTER WHEELS

- ▶ Again, width will define options
- ▶ 5,7,9,11
- ▶ What size filters do you need? What size is the sensor?
- ▶ Compatible with your Software?
- ▶ Insure proper connections with camera and OAG
- ▶ L,R,G,B,Ha,Oiii,Sii,Nii,Hb,IDAS, Black?, Moon?,

ADAPTERS/SPACERS

- ▶ Millimeters matter
- ▶ Know your needs - 42mm? 48? T? C?
- ▶ Try to plan to have mm's left over - and fill in with spacers
- ▶ Worst comes to worst: Precise Parts
- ▶ Stellarvue - great source of spacers
- ▶ Threaded connections are best
- ▶ Required back focus = x-adapter+OAG+FW+back-spacing of sensor

USED EQUIPMENT

- ▶ Typically 20-40% off new - often for perfect condition
- ▶ Prices stable (unless new model/technology), so can sell for purchase price - more or less.
- ▶ Most active sites:
 - ▶ Cloudy Nights - I've bought many things - never a bad experience; huge volume
 - ▶ Astromart - small yearly fee, tend to see higher quality gear
 - ▶ astrobuysell.com - Canada-based site.
 - ▶ Sky and Telescope Marketplace - pretty dead

SOFTWARE

- ▶ Most are platform dependent
- ▶ Free, or almost, Capture Software
 - ▶ Kstars/Ekos - all platforms - free, open source
 - ▶ <https://nighttime-imaging.eu> - N.I.N.A. - free, os
 - ▶ Sharpcap - PC (\$10/yr)
 - ▶ BackYard EOS/Nikon (\$50)
 - ▶ Nebulosity 4 (\$95) plus PHD2 (free guiding software)
 - ▶ Not free: Voyager, Sequence Generator Pro, The Sky X
- ▶ Free, or almost, Processing Software
 - ▶ Deep Sky Stacker (free) and GIMP (free photoshop)
 - ▶ Star Tools (\$50)
 - ▶ Astro Pixel Processor (\$150)
- ▶ PixInsight: \$250

MAKING CHOICES

- ▶ First: What do you want to accomplish?
 - ▶ Planetary/Moon
 - ▶ Bright Objects
 - ▶ Deep Sky
- ▶ What equipment do you already have?
- ▶ Scope/lens: Start with something **less than 600mm** focal length and **F/4-f/6**.
- ▶ Make sure to look at image scale, esp. if you are not heavily into post processing (Try to stay **under 1 arc-sec/pixel**)
- ▶ Choose bright objects and short exposures to start
 - ▶ Test your system to see when star trails start to appear
- ▶ Do research and ask questions - some equipment is notoriously frustrating.
